Sir,

The positions of the dental chair, patient and operator are critical for successful completion of tooth extraction. Whilst, the proper positioning of the operator is very important to have good visibility and accessibility of the oral cavity, besides allowing the surgeon to have maximal control of the force that is being delivered to the patient’s tooth through the forceps. Also, proper operating position and good posture reduces fatigue and physical strain and possibility of developing musculo-skeletal disorders.

For extraction of the mandibular right posterior teeth, a right-handed operator would usually stand at the right rear position (11 o’clock) or direct rear position (12 o’clock) [Figure 1]. These positions give good visibility and maximal accessibility to the oral cavity posteriorly as far as right first mandibular molar. However, a diminished accessibility is experienced by many operators when extracting the right second and third molars from these positions. It also results in unnecessary curvature of the spine or slumping of shoulders during the surgical procedure leading to physical strain [Figure 2].

With the intention to overcome this diminished accessibility and to enhance the effectiveness of the operator, the authors recommend positioning of a right-handed operator at the left rear position (2 o’clock) for extraction of the mandibular right posterior teeth [Figure 3]. This compatible operator position allows for good visibility and accessibility to the oral cavity posteriorly as far as the right first mandibular molar, while also reducing fatigue and physical strain.
