ABSTRACT

This study was conducted to evaluate changes in the composition of a poly-L-lactic D-lactic acid and trimethylene carbonate (PLDLA-TMC) sheet after insertion into the human body. A 35-year-old woman had an orbital fracture that was reconstructed using a PLDLA-TMC sheet. During iliac bone grafting for enophthalmos 190 days after the insertion, the sheet was removed and analyzed using gel permeation chromatography and Fourier transform infrared spectroscopy. The weight average molecular weight decreased (from 151,000 Da to 10,000 Da), as did the number average molecular weight (from 15,600 Da to 255 Da). An amide functional group peaks at 1,655.43 cm⁻¹ (1,670-1,640 cm⁻¹) and its stretch band at 1,541.26 cm⁻¹ (1,640-1,550 cm⁻¹) newly appeared due to serum or tissue fluid incorporation. PLDLA-TMC is expected to exhibit favorable degradation properties.
INTRODUCTION

Absorbable sheets are used to treat orbital fractures. CPS sheets [poly L-lactic D-lactic acid and trimethylene carbonate (PLDLA-TMC)] absorbable sheets (Inion Co., Tampere, Finland) are commonly used to treat trauma and in reconstructive procedures of the orbital cavity. In vivo degradation of several absorbable materials has been documented.[1-4] However, the compositional changes (appearance of radicals, etc.) of PLDLA-TMC after insertion into the human body have not yet been described.

The aim of this paper was to assess compositional changes in a PLDLA-TMC sheet, synthesized by a ring-opening polymerization process, 190 days after insertion into a human body.

CASE REPORT

Patient history and sample
A 35-year-old female patient had a pan-facial fracture due to a car accident. Upon examination, she did not show diplopia or hypoesthesia. A computed tomography scan showed a blow-out fracture of the right medial wall and floor with herniation of soft tissues [Figure 1].

Through a subciliary incision, the orbital floor and medial wall were exposed and the herniated soft tissues were reduced. The floor and medial wall were reconstructed with a trimmed (45 mm × 33 mm × 1.5 mm) CPS sheet made of PLDLA-TMC (Inion Co., Tampere, Finland) [Figure 2].

Exophthalmometry on postoperative day (POD) 9 revealed a 3-mm difference (right eye, 19 mm; left eye, 16 mm). The differences in exophthalmometry on POD 98 and POD 154 were 7 mm (right eye, 18 mm; left eye, 11 mm) and 8 mm (right eye, 19 mm; left eye, 11 mm), respectively. On POD 189 (1 day before the secondary operation), the difference was 5 mm (right eye, 18 mm; left eye, 13 mm).

Secondary reconstruction of the orbital floor was performed with an iliac bone graft 190 days after insertion. During the secondary operation, the fragile part of the CPS sheet that had been previously inserted was removed.

Analysis of molecular weight and components of the PLDLA-TMC sheet
The sample was analyzed using gel permeation chromatography (GPC) (Waters GPC system; Waters Co., Milford, MA, USA) to characterize changes in its molecular weight.

Fourier transform infrared spectroscopy (FT-IR) (JASCO FT-IR 4100; JASCO Co., Tokyo, Japan) was used to evaluate compositional changes that occurred due to being in the body.

The principles outlined in the Declaration of Helsinki were followed in this study.

Gel permeation chromatography
In the specimen from the operation, the weight average molecular weight (Mw) decreased from 151,000 Da to 10,000 Da, and the number average molecular weight (Mn) decreased from 15,600 Da to 255 Da. The polydispersity index (Mn/Mw) thus increased from 9.96 to 40.22 [Figure 3].

Fourier transform infrared spectroscopy
In the post-insertion spectrum, 1,655.43 cm⁻¹ and 1,541.26 cm⁻¹ peaks appeared, which are thought to be an amide peak (1,670-1,640 cm⁻¹) and its stretch bend (1,640-1,550 cm⁻¹), respectively [Figure 4].

DISCUSSION

Matsumura prepared poly(lactide-co-trimethylene carbonate) through the lipase-catalyzed ring-opening copolymerization of lactide and trimethylene carbonate, increasing the carbonate content from 0 to 100%.[5]
Yang et al. reported that hemolysis tests showed that all homopolymers and copolymers presented very low hemolytic ratios, indicating good hemolytic properties. Adhesion and activation of platelets were observed on the surface of polylactic acid, polycaprolactone (PCL), poly L-lactic acid (PLLA) and trimethylene carbonate (TMC) (PLLA-TMC), and poly-DL-lactide (PDLLA)-TMC films, while fewer platelets and less activation were found on poly(TMC). The most interesting results were obtained with PCL-TMC, which exhibited the lowest degree of activation, with few adhered platelets, in agreement with its outstanding anticoagulant properties.

Guo et al., in an experiment using 144 Wistar rats, stated that the molecular weight of PLLA decreased rapidly, from 72,000 to 68,000 kDa in the first 2 days and to 32,000 kDa 15 days later. Similar molecular weight decreases were obtained for PLLA-TMC and PDLLA-TMC copolymers, although PLLA-TMC appeared more resistant to hydrolytic degradation. Beyond 60 days, the molecular weight of PDLLA-TMC decreased below 10,000 kDa, in agreement with the rapid mass loss observed in this period. In our study, GPC was used to find that the Mw of PLDLA-TMC decreased from 151,000 Da to 10,000 Da 190 days after insertion. This suggests that PLDLA-TMC has favorable degradation properties.

Originally, PDLLA-TMC did not have an amide peak (1,670-1,640 cm⁻¹) or its stretch bend (1,640-1,550 cm⁻¹). In our study, FT-IR of the post-insertion spectrum showed new 1,655.43 cm⁻¹ and 1,541.26 cm⁻¹ peaks, which are thought to be an amide peak (1,670-1,640 cm⁻¹) and its stretch bend (1,640-1,550 cm⁻¹), respectively.
Chapanian and Amsden\textsuperscript{[10]} investigated the potential of osmotic pressure-driven release of proteins from poly(TMC-co-DLLA) elastomers with varying amounts of DLLA, using bovine serum albumin (BSA) as a model protein. The BSA was co-lyophilized with either trehalose or trehalose combined with sodium chloride as osmotigens to produce particles with sufficient osmotic activity.

The reduced molecular weights in the post-insertion specimen suggest that PLDLA-TMC has favorable degradation properties. The newly appeared bands are thought to be an amide peak (1,670-1,640 cm\(^{-1}\)) and its stretch bend (1,640-1,550 cm\(^{-1}\)), resulting from serum or tissue fluid incorporation.
