The application of stem cells technology to the intractable disease has emerged in the 21st century. It has been applied to almost all areas of medicine, including cardiovascular, nervouslogic, hematologic, genetic, liver, endocrine and musculoskeletal diseases. In particular, stem cell mediated tissue regeneration has opened treatment options for previously-considered intractable diseases, with no other treatment alternatives.

Stem cells have the ability of self-replicating and differentiate into cells that make up various post-embryonic organ systems. They play an important role in regeneration of organs and tissues throughout life. There are two basic types of stem cells: embryonic stem cells derived from blasto-cytes, and adult stem cells obtained from fully developed adult tissue or placenta. Embryonic stem cells proliferate with ease due to great self-replicating ability of their undifferentiated state. However, applying this knowledge raises ethical problems. Therefore, studies on adult stem cells are in progress.

Bone marrow-derived stem cells are one of better-characterized adult stem cells.[1,2] However, harvesting these bone marrow remains a challenge, and their isolation and yield ability is relatively low. For sufficient amounts of clinical use, multiple samples are required. Therefore, researchers have begun to explore new alternative sources of stem cells. Zuk et al.[3] reported...
multi-lineage cells isolated from adipose tissues called stromal vascular fractions, which are assumed to be stem cells and named the cells “processed lipoaspirate.” Lately, these “processed lipoaspirate” cells have come to be called adipose tissue-derived stromal cells, or adipose tissue-derived stem cells (ASCs).[4,5] These cells, after being extracted and separated from adipose tissue, show stable growth and proliferation in culture environments, and have the capability of differentiating into various cell types, just like marrow stem cells.[6]

The authors reviewed 118 articles regarding ASCs using PubMed and Cochrane databases. They summarized: (1) immunophenotypic properties; (2) cell yield; (3) angiogenic effect; (4) effects on wound healing; and (5) immune modulation effect of ASCs. They raised a question of whether stem cell function alone or via a paracrine effect. Jun et al.[6] reported that the effects of ASCs on neuronal regeneration might be caused by both the stem-cell itself, and a paracrine effect. The ability of mesenchymal stem cells to differentiate has been also reported to vary according to the tissue of origin, or the donor’s age.[7] However, the theory that the origin of the fat extract, gender, or age of the donor may affect the characteristic of differentiation is not yet supported by sufficient data.

In the authors’ paper, ASCs have the ability to differentiate into several cell lineages, improve wound healing, and promote angiogenesis. I believe this study will be used to establish better applications of ASC therapy in the future.
